In recent years, there has been developed and put to practical use a large-capacity synchronous DRAM, in which one memory cell is composed of one MOS transistor and one capacitor. In such a large-capacity synchronous DRAM, it is essential to raise a drive capability of a word line to be capable of driving a capacitance of a memory cell. However, this is accompanied by an increase in the area of a chip of the DRAM. Accordingly, in order to further increase the capacity of the DRAM, it is necessary to reduce the area of the chip. In order to accomplish this, it is necessary to reduce a contact area of the memory cell, i.e., a node of the capacitor, a source region of the MOS transistor, and a gate electrode of the MOS transistor. In this case, it is necessary to raise the drive capability of a word line to prevent an increase in the junction capacity.Dosage compensation of X chromosomes in mammals.
