The pharmaceutical industry has to provide a return on the investment of millions of dollars that goes into drug development. The major driver is how effective a molecule is in a specific disease and how well it performs in clinical trials. However, a major problem in drug discovery is that the traditional approach used by the industry to discover new drugs is frequently an inefficient process. The current paradigm is to pre-screen and identify a compound that has desirable pharmacological activity in vitro and preclinical safety in animal studies. This information is then used to guide the search for a compound with clinical properties. A basic problem is that the pharmacology, toxicology and clinical activity are all different characteristics and have nothing to do with each other. The industry is using small molecule pharmaceuticals that were selected for pre-clinical safety and efficacy. Despite this, the clinical activity for compounds tested in animal models is only 1-5% of the compounds in the animal studies and with a similar failure rate in clinical trials. This lack of chemical similarity between the compounds in animal models and in humans is due to the focus of medicinal chemistry on a fragment of the parent molecule as a starting point for structure 2d92ce491b
